Transaction Management Part II: Recovery

Shan Hung Wu & DataLab CS, NTHU

Today's Topic: Recovery Mgr

VanillaCore

Failure in a DBMS

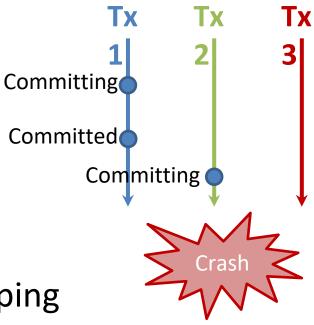

- Types:
 - Disk crash, power outage, software error, disaster (e.g., a fire), etc.
- In this lecture, we consider only:
 - Transaction hangs
 - Logical hangs: e.g., data not found, overflow, bad input
 - System hangs: e.g., deadlock
 - System hangs/crashes
 - Hardware error, or a bug in software that hangs the DBMS

Assumptions about Failure

- Contents in nonvolatile storage are *not corrupted*
 - E.g., via file-system journaling
- No Byzantine failure (zombies)
- Other types of failure will be dealt with in other ways
 - E.g., via replication, quorums, etc.

- D given buffers?
- Flush all dirty buffers of a tx *before* committing the tx and returning to the DBMS client

- What if system crashes and then restarts?
- To ensure A, DBMS needs to rollback uncommitted txs (2 and 3) at sart-up
 - Why 3? flushes due to swapping
- Problems:
 - How to determine which txs to rollback?
 - How to rollback all actions made by a tx?

- Idea: Write-Ahead-Logging (WAL)
 - Record a *log* of each modification made by a tx
 - E.g., <SETVAL, <TX>, <BLK>, <OFFSET>, <VAL_TYPE>,
 <OLD_VAL> >
 - In memory to save I/Os
 - To commit a tx,
 - Write all associated logs to a log file *before* flushing a buffer
 - 2. After flushing, write a <COMMIT, <TX>> log to the log file
 - To swap a dirty buffer (in BufferMgr)
 - All logs must be flushed *before* flushing a buffer

- Which txs to rollback?
 - Observation: txs with COMMIT logs must have flushed all their dirty blocks
 - Ans: those without COMMIT logs in the log file
- How to rollback a tx?
 - Observation: each action on the disk:
 - 1. With log and block
 - 2. With log, but without block
 - 3. Without log and block
 - Ans: simply *undo* actions that are logged to disk, flush all affected blocks, and then writes a <ROLLBACK, <TX>> log

- Assumption of WAL: each block-write either succeeds or fails entirely on a disk, despite power failure
 - I.e., no corrupted log block after crash
 - Modern disks usually store enough power to finish the ongoing sector-write upon power-off
 - Valid if block size == sector size or a journaling file system (e.g., EXT3/4, NTFS) is used
 - Block/physical vs. metadata/logical journals

Review: Caching Logs

- Like user blocks, the blocks of the log file are cached
 - Each tx operation is logged *into memory*
 - To avoid excessive I/Os
- Log blocks are flushed only on either
 - Tx commit, or
 - Flushing of data buffer

System Components related to Recovery

- The *log manager* manages the caching for logs
 Does not understand the semantic of logs
- The *buffer manager* ensures WAL for each flushed data buffer
- The *recovery manager* ensures A and D by deciding:
 - What to log (semantically)
 - When to flush buffers (and log tails)
 - How to rollback a tx
 - How to recover a DB from crash

Actions of Recovery Manager

- Actions during normal tx processing:
 - Adds log records to cache
 - Flushes log tail and buffers at COMMIT
 - Or, rolls back txs
 - By undoing changes made by each tx
 - On behalf of *normal txs*
- Actions after system re-start (from a failure):
 - Recovers the database to a consistent state
 - By undoing changes made by all incomplete tx
 - In a *dedicated recovery tx* (before all normal txs start)

Txn B:

Write y = 10; Read x; If (x>=4) Write x=x+1; else Rollback; Commit;

Outline

- Physical logging:
 - Logs and rollback
 - UNDO-only recovery
 - UNDO-REDO recovery
 - Failures during recovery
 - Checkpointing
- Logical logging:
 - Early lock release and logical UNDOs
 - Repeating history
- Physiological logging
- RecoveryMgr in VanillaCore

Outline

- Physical logging:
 - Logs and rollback
 - UNDO-only recovery
 - UNDO-REDO recovery
 - Failures during recovery
 - Checkpointing
- Logical logging:
 - Early lock release and logical UNDOs
 - Repeating history
- Physiological logging
- RecoveryMgr in VanillaCore

Log Records

- In order to be able to roll back a transaction, the recovery manager saves information in the log
- Recovery manager add a *log record* to the log cache each time a loggable activity occurs
 - Start
 - Commit
 - Rollback
 - Update record
 - Checkpoint

Log Records

Txn 27:

start; getVal(blk0, 46); setVal(blk1, 58, "abc"); commit;

- The log records of txn 27: <START, 27> <SETVAL, 27, student.tbl, 1, 58, 'kay', 'abc'> <COMMIT, 27> offset
- In general, multiple txns will be writing to the log concurrently, and so the log records for a given txn will be dispersed throughout the log

```
<START, 27>
<ROLLBACK, 23>
<START, 28>
<SETVAL, 28, dept.tbl, 23, 0, 1, 5>
<SETVAL, 27, student.tbl, 1, 58, 'kay', 'abc'>
<COMMIT, 27>
```

• • •

Why COMMIT/ROLLBACK Logs?

- Used to identify incomplete txs during recovery
- Incomplete txs?
 - E.g., those without COMMIT/ROLLBACK logs on disk
 - To be discussed later

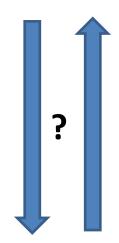

Flushing COMMIT

- When committing a tx, the COMMIT log must be flushed *before* returning to the user
 - Why? public void onTxCommit(Transaction tx) {
 VanillaDb.bufferMgr().flushAll(txNum);
 long lsn = new CommitRecord(txNum).writeToLog();
 VanillaDb.LogMgr().flush(Lsn);
 }
- What if the system returns to the client but crashes before writing a commit log?
 - The recovery manager will treat it as an incomplete tx and undo all its changes
 - Dangers durability

Rollback

- The recovery manger can use the log to roll back a tx by *undoing* all tx's modifications
- How to undo txn 27?

```
<START, 27>
<ROLLBACK, 23>
<START, 28>
<SETVAL, 28, dept.tbl, 23, 0, 1, 5>
<SETVAL, 27, student.tbl, 1, 58, `kay', `abc'>
<SETVAL, 27, dept.tbl, 2, 40, 9, 25>
...
```

Rollback

• Undo txn 27

```
<SETVAL, 23, dept.tbl, 10, 0, 15, 35>
<START, 27>
                            ensures the correctness of multiple modifications
<SETVAL, 27, dept.tbl, 2, 40, 15, 9>
<ROLLBACK, 23>
<START, 28>
                                                 restores old values
<SETVAL, 28, dept.tbl, 23, 0, 1, 5>
<SETVAL, 27, student.tbl, 1, 58, 'kay', 'abc'>
<SETVAL, 27, dept.tbl, 2, 40, 9, 25>
<START, 29>
ROLLBACK, 27><sup>undo starts from log tail</sup>
                   The log records of T are more likely to be at the end of log file
```

Rollback

- The algorithm for rolling back txn T
 - 1. Set the current record to be the most recent log record
 - 2. Do until the current record is the start record for *T*:
 - a) If the current record is an update record for *T*, then write back the old value
 - b) Move to the previous record in the log
 - 3. Flush all dirty buffers made by T
 - 4. Append a rollback record to the log file
 - 5. Return

Codes for Rollback

```
public void onTxRollback(Transaction tx) {
    doRollback();
    VanillaDb.bufferMgr().flushAll(txNum);
     long lsn = new RollbackRecord(txNum).writeToLog();
    VanillaDb.LogMgr().flush(lsn);
}
private void doRollback() {
    Iterator<LogRecord> iter = new LogRecordIterator();
    while (iter.hasNext()) {
         LogRecord rec = iter.next();
         if (rec.txNumber() == txNum) {
              if (rec.op() == OP START)
                   return;
              rec.undo(txNum);
         }
     }
}
```

Working with Locks

- When a tx T that is rolling back, recovery manager requires the DBMS to prevent any access (by other txs) to the data modified by T
 - Otherwise, undoing an operation of T may override later modifications
- Can easily be enforced by, for example, S2PL

Working with Memory Managers

- No tx should be able to modify the buffer when that buffer, and its logs, are being flushed; and vise versa
- How?
- For each block, pinning and flushing contend for a short-term X lock, called *latch*

Latching on Blocks

- To modify a block:
 - 1. Acquire the latch of that block
 - 2. Log the update (in memory, done by LogMgr)
 - 3. Perform the change
 - 4. Release the latch
- To flush a buffer containing a block:
 - 1. Acquire the latch of that block (after pin())
 - 2. Flush corresponding log records
 - 3. Flush buffer
 - 4. Release the latch
- Latches have *nothing* to do with
 - Locks in S2PL
 - Pinning/unpinning in BufferMgr

Outline

• Physical logging:

- Logs and rollback
- UNDO-only recovery
- UNDO-REDO recovery
- Failures during recovery
- Checkpointing
- Logical logging:
 - Early lock release and logical UNDOs
 - Repeating history
- Physiological logging
- RecoveryMgr in VanillaCore

Recovery

- When the DMBS restart (from crash), the recovery manager is responsible for restoring the database
 - All incomplete txs should be *rolled back*
- How to identify incomplete txs?

Incomplete Txs (1)

 Recall that when committing/rolling back a tx, the CIMMIT/ROLLBACK log must be flushed before returning to the user

```
public void onTxCommit(Transaction tx) {
    VanillaDb.bufferMgr().flushAll(txNum);
    long lsn = new CommitRecord(txNum).writeToLog();
    VanillaDb.logMgr().flush(lsn);
}
```

```
public void onTxRollback(Transaction tx) {
    doRollback();
    VanillaDb.bufferMgr().fLushAll(txNum);
    long lsn = new RollbackRecord(txNum).writeToLog();
    VanillaDb.LogMgr().fLush(Lsn);
}
```

Incomplete Txs (2)

- Definition: txs without COMMIT or ROLLBACK records in the log file on disk
- Could be in any of following states when crash happens:
 - 1. Active
 - 2. Committing (but not completed yet)
 - 3. Rolling back

Undo-only Recovery Algorithm

- 1. For each log record (reading backwards from the end):
 - a) If the current record is a commit record then:

Add that transaction to the list of committed transactions.

b) If the current record is a rollback record then:

Add that transaction to the list of rolled-back transactions.

c) If the current record is an update record and that transaction is not on the committed or rollback list, then:

Restore the old value at the specified location.

Undo-only Recovery

Undo and redo

Completed Txn: 27

```
older Beginning of log
    <START, 23>
    <SETVAL, 23, dept.tbl, 10, 0, 15, 35>
    <START, 27>
    <COMMIT, 23>
    <SETVAL, 27, dept.tbl, 2, 40, 15, 9>
    <START, 28>
    <SETVAL, 28, dept.tbl, 23, 0, 1, 5>
    <SETVAL, 27, student.tbl, 1, 58, 4, 5>
    <SETVAL, 27, dept.tbl, 2, 40, 9, 25>
    <START, 29>
    <SETVAL, 29, emp.tbl, 1, 0, 1, 9>
                                                 undo
    <ROLLBACK, 27>
```

Undo-only Recovery

Undo and redo

Completed Txn: 27

```
older Beginning of log
    <START, 23>
    <SETVAL, 23, dept.tbl, 10, 0, 15, 35>
    <START, 27>
    <COMMIT, 23>
    <SETVAL, 27, dept.tbl, 2, 40, 15, 9>
    <START, 28>
    <SETVAL, 28, dept.tbl, 23, 0, 1, 5>
<SETVAL, 27, student.tbl, 1, 58, 4, 5>
                                                      undo
    <SETVAL, 27, dept.tbl, 2, 40, 9, 25>
    <START, 29>
    <SETVAL, 29, emp.tbl, 1, 0, 1, 9>
    <ROLLBACK, 27>
```

Undo-only Recovery Algorithm

```
public void recover() { // called on start-up
    doRecover();
    VanillaDb.bufferMgr().flushAll(txNum);
    long lsn = new CheckpointRecord().writeToLog();
    VanillaDb.logMgr().flush(lsn);
}
private void doRecover() {
    Collection<Long> finishedTxs = new ArrayList<Long>();
    Iterator<LogRecord> iter = new LogRecordIterator();
    while (iter.hasNext()) {
         LogRecord rec = iter.next();
         if (rec.op() == OP CHECKPOINT)
              return;
         if (rec.op() == OP COMMIT || rec.op() == OP ROLLBACK)
              finishedTxs.add(rec.txNumber());
         else if (!finishedTxs.contains(rec.txNumber()))
              rec.undo(txNum);
    }
}
```

• Flushing and checkpointing will be explained later

Working with Other System Components

- No special requirement since the recovery tx is the *only* tx in system at startup
 - Normal txs start only *after* the recovery tx finishes

The above RecoveryMgr will make system unacceptably slow!

Outline

• Physical logging:

- Logs and rollback
- UNDO-only recovery

UNDO-REDO recovery

- Failures during recovery
- Checkpointing
- Logical logging:
 - Early lock release and logical UNDOs
 - Repeating history
- Physiological logging
- RecoveryMgr in VanillaCore

Why Slow?

- Slow commit
 - Flushes: undo logs, dirty blocks, and then COMMIT log
- Slow rollback
 - Flushes: dirty blocks and ROLLBACK log
- Slow recovery
 - Recovery manager need to scan the entire log file (backward from tail) every time

Force vs. No-Force

- Force approach
 - When committing tx, all modifications need to be written to disk *before* returning to user
- When client committing a txn
 - 1. Flush the logs till the LSN of the last modification
 - 2. Flush dirty pages
 - 3. Write a COMMIT record to log file on disk
 - 4. Return

Force vs. No-Force

- Do we really need to flush all dirty blocks when committing a tx?
- Why not just write logs?
 No flushing data blocks → faster commit
- Problem: committed txs may not be reflected to disk
 - Lost once system crashes
- Solution: a new *redo* phase in recovery?

– To reconstruct buffer state in memory

new value

Undo and redo

```
older Beginning of log

• Undo and redo

Completed Txn: 27, 23

The Undo-Redo Recovery Algorithm V1

// The undo stage

- 1. For each log record (reading backwards from the end):
 - a) If the current record is a commit record then:

Add that transaction to the list of committed transactions.

b) If the current record is a rollback record then:

Add that transaction to the list of rolled-back transactions.

c) If the current record is an update record and that transaction is not on the committed or rollback list, then:

Restore the old value at the specified location.

// The redo stage

 For each log record (reading forwards from the beginning): If the current record is an update record and that transaction is on the committed list, then:

Restore the new value at the specified location.

Figure 14-6

The undo-redo algorithm for recovering a database

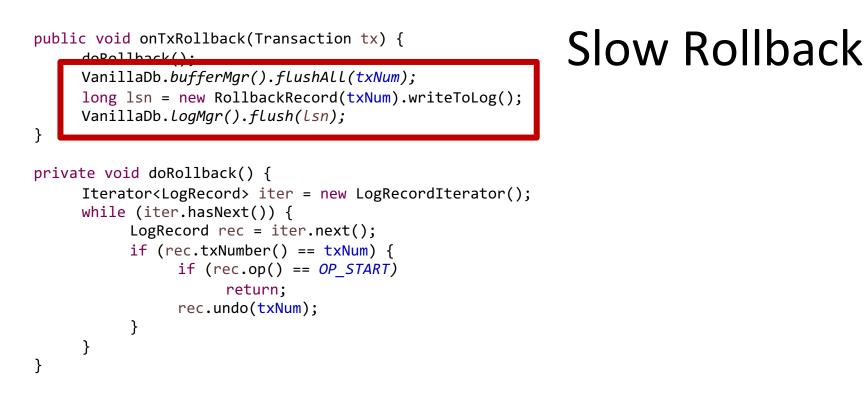

Physical Logging

- Undo/redo operations are *idempotent*
 - Executing same undo op multiple times = one time execution
- Some actions may be unnecessary or redundant
 - Depending on swapping state in buffer manager
 - No harm to C

Can We Make Rollback Faster Too?

 Recall that when rolling back a tx, we flush dirty pages and write a rollback log

```
public void onTxRollback(Transaction tx) {
    doRollback();
    VanillaDb.bufferMgr().flushAll(txNum);
    long lsn = new RollbackRecord(txNum).writeToLog();
    VanillaDb.LogMgr().flush(lsn);
}
private void doRollback() {
    Iterator<LogRecord> iter = new LogRecordIterator();
    while (iter.hasNext()) {
         LogRecord rec = iter.next();
         if (rec.txNumber() == txNum) {
              if (rec.op() == OP START)
                   return;
              rec.undo(txNum);
         }
     }
}
```

- Why flushing dirty buffers?
 - So the recovery tx can skip txs that have been rolled back
- Can we skip it?

Fast Rollback

- No-force:
 - Do *not* flush dirty pages during rollback
 - In addition, there's *no* need to keep the ROLLBACK record in cache at all!
- Aborted txs will be rolled back again during startup recovery
 - No harm to C since undo operations are idempotent

The Undo-Redo Recovery Algorithm V2

// The undo stage

1. For each log record (reading backwards from the end):

a) If the current record is a commit record then:

No (b). All txs not in the committed list are un-done (maybe again)

b) If the current record is a rollback record then:

Add that transaction to the list of rolled-back transactions.

c) If the current record is an update record and that transaction is not on the committed or rollback list, then:

Restore the old value at the specified location.

// The redo stage

2. For each log record (reading forwards from the beginning):

If the current record is an update record and that transaction is on the committed list, then:

Restore the new value at the specified location.

Figure 14-6

The undo-redo algorithm for recovering a database

Undo or Redo Phase First?

- Does not matter for the recovery algorithm V1
- But matters for V2!
 - Undo phase *must precede* the redo phase
 - Otherwise, C may be damaged due to aborted txs

```
— E. g.,
```

```
<START, 23>
<SETVAL, 23, dept.tbl, 10, 0, 15, 35>
// T23 rolls back (not logged) and releases locks
<START, 27>
<SETVAL, 27, dept.tbl, 10, 0, 15, 40>
<COMMIT, 27>
```

Rolling back T23 erases the modification made by T27

Undo-Only vs. Undo-Redo Recovery

- Pros of undo-only:
 - Faster recovery
 - No redo logs
- Cons of undo-only:
 - Slower commit/rollback
- Which one?
 - Commercial DBMSs usually choose no-force approach + undo-redo recovery

Steal vs. No Steal

- Currently, dirty buffers can be flushed to disk before tx commit
 - Due to swapping
 - Steal approach
- If no steal, then we don't need undo phase!
 Redo-only recovery
- How?

– Pin all the modified buffers until tx ends?

No redo, no undo with force + no steal?

Redo-Only Recovery and Beyond

- No-steal is not practical
- Dirty pages still need to be flushed before commits
 - To ensure durability
- How about crash during flushing?

Outline

• Physical logging:

- Logs and rollback
- UNDO-only recovery
- UNDO-REDO recovery

Failures during recovery

- Checkpointing
- Logical logging:
 - Early lock release and logical UNDOs
 - Repeating history
- Physiological logging
- RecoveryMgr in VanillaCore

What if system crashes again during recovery?

Can we simply re-run recovery (from scratch) after restart?

Idempotent Recovery

- Yes! Since each undo/redo is idempotent
- No need to log undos/redos
 - For each data modification due to undo/redo, recovery manager passes -1 as the LSN number to the buffer manager
 - See SetValueRecord.undo()

Outline

• Physical logging:

- Logs and rollback
- UNDO-only recovery
- UNDO-REDO recovery
- Failures during recovery

Checkpointing

- Logical logging:
 - Early lock release and logical UNDOs
 - Repeating history
- Physiological logging
- RecoveryMgr in VanillaCore

Checkpointing

- As the system keeps processing requests, the log file may become very large
 - Running recovery process is time consuming
 - Can we just read a portion of the log?
- A *checkpoint* is like a consistent snapshot of the DBMS state
 - All earlier log records were written by "completed" txns
 - Those txns' modifications have been flushed to disk
- During recovery, the recovery manager can ignore all the log records before a checkpoint

Quiescent Checkpointing

- 1. Stop accepting new transactions
- 2. Wait for existing transactions to finish
- 3. Flush all modified buffers
- 4. Append a quiescent checkpoint record to the log and flush it to disk
- 5. Start accepting new transactions

Quiescent Checkpointing

```
<START, 0>
 <SETINT, 0, student.tbl, 0, 38, 2004, 2005>
 <START, 1>
 <START, 2>
 <COMMIT, 1>
 <SETSTRING, 2, junk, 44, 20, hello, ciao>
       //The guiescent checkpoint procedure starts here
 <SETSTRING, 0, student.tbl, 0, 46, amy, aimee>
 <COMMIT, 0>
       //tx 3 wants to start here, but must wait
 <SETINT, 2, junk, 66, 8, 0, 116>
 <COMMIT, 2>
                                        Undo Redo
 <CHECKPOINT>
 <START, 3>
 <SETINT, 3, junk, 33, 8, 543, 120>
Figure 14-10
A log using quiescent checkpointing
```

Quiescent Checkpointing is Slow

 Quiescent checkpointing is simple but may make the system unavailable *for too long* during checkpointing process

Root Cause of Unavailability

- 1. Stop accepting new transactions
- 2. Wait for existing transactions to finish
- 3. Flush all modified buffers *May be very long!*
- 4. Append a quiescent checkpoint record to the log and flush it to disk
- 5. Start accepting new transactions

Can we shorten the quiescent period?

Nonquiescent Checkpointing

- **1**. Stop accepting new transactions
- 2. Let T_1, \ldots, T_k be the currently running transactions
- 3. Flush all modified buffers
- 4. Write the record < NQCKPT, $T_1, ..., T_k > and$ flush it to disk
- 5. Start accepting new transactions

Recovery with Nonquiescent Checkpointing

• Txs not in checkpoint log are flushed thus can be neglected

```
<START, 0>
       <SETINT, 0, student.tbl, 0, 38, 2004, 2005>
       <START, 1>
       <START, 2>
       <COMMIT, 1>

SETSTRING, 2, junk, 44, 20, hello, ciao>

       <u>NOCKPT</u>, 0, 2> Only tx2 needs to be undone
Redo
       SETSTRING, 0, student.tbl, 0, 46, amy, aimee>
       <COMMIT, 0> Tx0 has been committed
       <START, 3>
       <SETINT, 2, junk, 66, 8, 0, 116>
       SETINT, 3, junk, 33, 8, 543, 120>
Und
     Figure 14-12
     A log using nonquiescent checkpointing
```

Working with Memory Managers

- No tx should be able to
 - 1. append the log, and
 - 2. modify the buffer between steps 3 and 4
- How?
- The checkpoint tx obtains
 - 1. latch of log file, and
 - 2. latches of all blocks in BufferMgr
 - before step 3
- Then release them after step 4

When to Checkpoint?

- By taking checkpoints periodically, the recovery process can become more efficient
- When is a good time to checkpoint?
 - During system startup (after the recovery has completed and before any txn has started)

```
public void recover() { // called on start-up
        doRecover();
        VanillaDb.bufferMgr().fLushALL(txNum);
        long lsn = new CheckpointRecord().writeToLog();
        VanillaDb.LogMgr().fLush(Lsn);
   }
```

- Execution time with *low workload* (e.g., midnight)

Outline

- Physical logging:
 - Logs and rollback
 - UNDO-only recovery
 - UNDO-REDO recovery
 - Failures during recovery
 - Checkpointing
- Logical logging:
 - Early lock release and logical UNDOs
 - Repeating history
- Physiological logging
- RecoveryMgr in VanillaCore

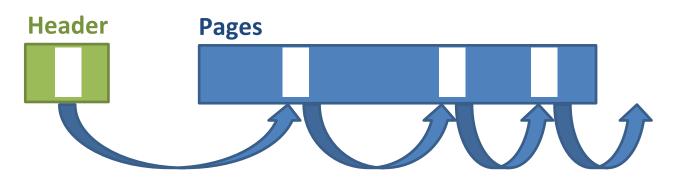

Early Lock Release

- There are meta-structures in a DBMS
 - E.g., FileHeaderPage in a RecordFile
 Indices
- Poor performance if they are locked in strict manner
 - E.g., S2PL on FileHeaderPage serializes all insertions and deletions
- Locks on meta-structures are usually *released early*

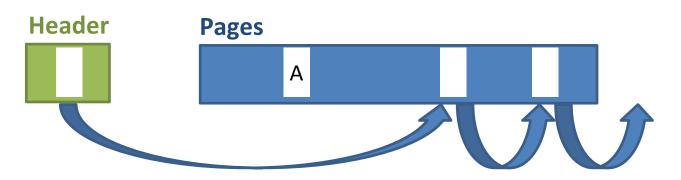

Logical Operations

- *Logical insertions* to a RecordFile:
 - Acquire locks of FileHeaderPage and target
 object (RecordPage or a record) in order
 - Perform insertion
 - Release the lock of FileHeaderPage (but not the object)
- Better concurrency for I
- No harm to C
- Needs special care to ensure A and D

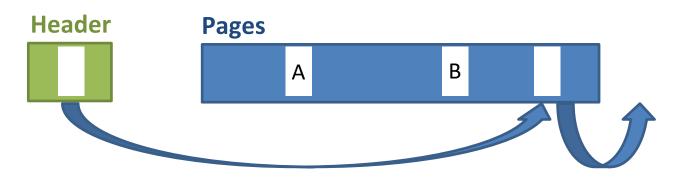

- 1. T1 inserts a record A to a table/file
 - FileHeaderPage and a RecordPage modified
- 2. T2 inserts another record B to the same table
 - Same FileHeaderPage and another RecordPage modified
- 3. T1 aborts
- If the physical undo record is used to rollback *T1, B* will be lost!

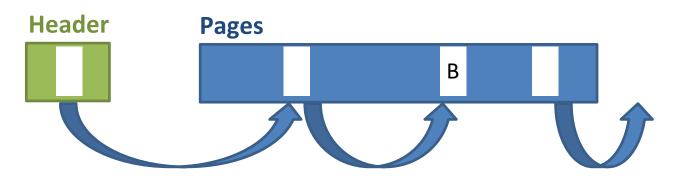

- 1. T1 inserts a record A to a table/file
 - FileHeaderPage and a RecordPage modified
- 2. T2 inserts another record B to the same table
 - Same FileHeaderPage and another RecordPage modified
- 3. T1 aborts
- If the physical undo record is used to rollback *T1, B* will be lost!

- 1. T1 inserts a record A to a table/file
 - FileHeaderPage and a RecordPage modified
- 2. T2 inserts another record B to the same table
 - Same FileHeaderPage and another RecordPage modified
- 3. T1 aborts
- If the physical undo record is used to rollback *T1, B* will be lost!

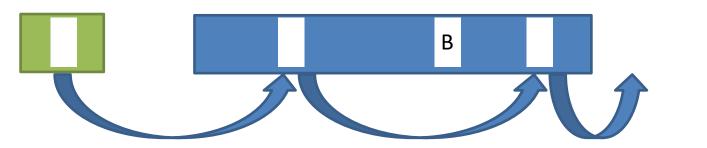

- 1. T1 inserts a record A to a table/file
 - FileHeaderPage and a RecordPage modified
- 2. T2 inserts another record B to the same table
 - Same FileHeaderPage and another RecordPage modified
- 3. T1 aborts
- If the physical undo record is used to rollback *T1, B* will be lost!

Undoing Logical Operations

- How to rollback *T1*?
 - By executing a *logical deletion* of record A

Logical operations need to be undone logically

Undoing Partial Logical Ops

- What if *T1* aborts in the middle of a logical operation?
- Log each physical operation performed during a logical operation
- So partial logical operation can be undone, by ^{older} undoing the physical operations

 Beginning of log

```
<START, T1>
<SETVAL, T1, RC, 15, 35>
<OPBEGIN, T1, OP1> // insert a record Identifier can be LSN
<SETVAL, T1, H, 100, 105>
<SETVAL, T1, RA, 0, 700>
<OPEND, T1, OP1, delete RA>
... // other tx can access H (early lock release)
```

Rolling Back a Transaction

- Undo OP1 using physical logs if it is not completed yet

 Locks of physical objects are not released so nothing can go wrong
- OP1 must be undone logically once it is complete
 - Some locks may be released early (e.g., lock of H)
 - Must acquire the locks again during logical undo

Let's consider crashes now...

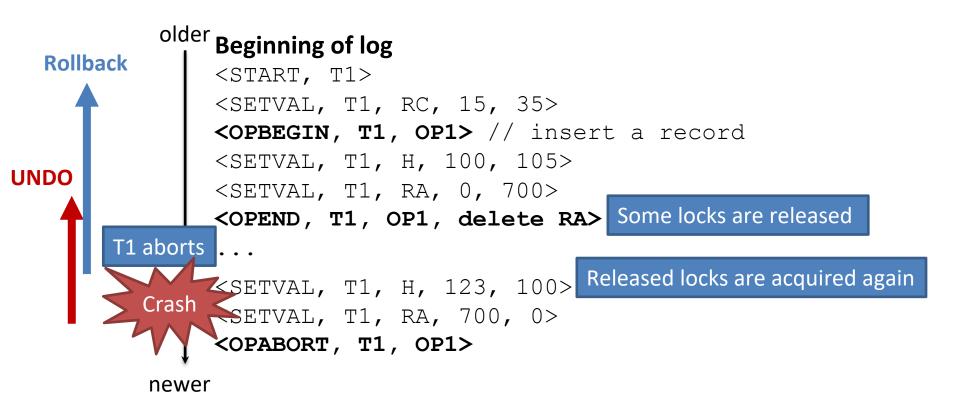

- UNDO: to roll back all uncommitted txs (and logical OPs)
- REDO: reconstruct memory state

• Unfortunately, it's not that simple...

Undo an Undo

- What if system crashes when T1 is undoing a logical op?
- The "undo" is *not* idempotent
 - The undo needs to be undone
- How?
- The undo is itself an logical operation
- Why not log all the physical operations of such an undo?
 - The logical undo can be undone now
 - Then, at recovery time, logically undo the target logical operation again

Undo an Undo

Can we apply UNDO/REDO recovery now?

Crashes

- Two goals of restart recovery:
 - Rolling back incomplete txs
 - Reconstruct memory state
- Handled by UNDO and REDO phase respectively
- Undo-redo recovery algorithm does *not* work anymore!
- Why?
- Since locks may be released early, physical logs may depend on each other
- Undoing/redoing physical logs must be carried out in the order they happened to ensure C

	Beginning of log <start, t1=""></start,>	Example
Rollback	<pre><setval, 15,="" <opbegin,="" op1="" rc,="" t1,=""> // <setual =="==================================</td"><td>insert a record</td></setual></setval,></pre>	insert a record
	<pre><setval, 0,="" 100,="" 7="" <opend,="" <setval,="" delege<="" h,="" op1,="" pre="" ra,="" t1,=""></setval,></pre>	
		record (changing H), l changes, and then commits
	<setval, 123,<="" h,="" t1,="" td=""> <setval, 700,<="" ra,="" t1,="" td=""></setval,></setval,>	
Cras	h ≪opabort, T1, Op1>	

- To carry out the last two physical ops (i.e., "undo of undo")
 T2 needs to be redone physically *first*
- Redoing T2 requires T1 to be redone *partially*, even if T1 will be rolled back eventually

Outline

- Physical logging:
 - Logs and rollback
 - UNDO-only recovery
 - UNDO-REDO recovery
 - Failures during recovery
 - Checkpointing
- Logical logging:
 - Early lock release and logical UNDOs
 - Repeating history
- Physiological logging
- RecoveryMgr in VanillaCore

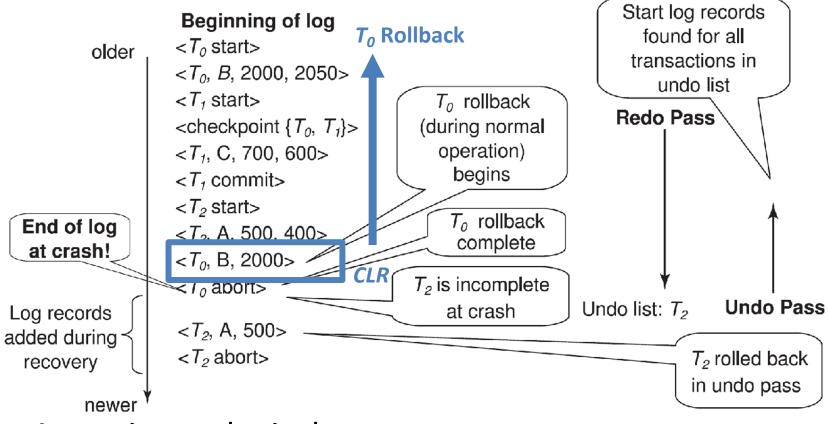

Recovery by Repeating History

- Idea:
 - Repeat history: replay all dependent physical operations (from the last checkpoint) *following the exact order they happened*
 - Including ongoing rollbacks/undos
 - So the memory state can be reconstructed correctly
 - 2. *Resume* rolling back all incomplete txs
 - Logically for each completed logical operation
- This leads to the state-of-the-art recovery algorithm, *ARIES*
- Steps 1/2 are called REDO/UNDO phase in ARIES
 - Very different from REDO/UNDO phase in previous sections

Compensation Logs

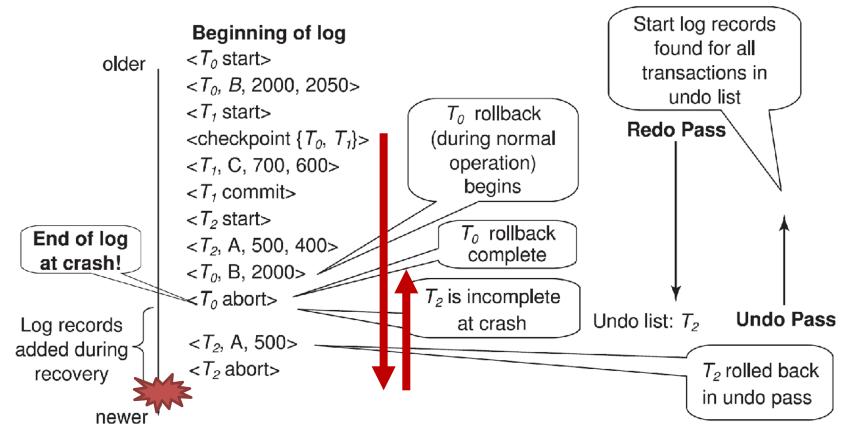

- Replaying history includes replaying previous undos
 - There may be previous *undos for some physical ops* (due to, e.g., tx rollbacks or crashes)
 - Need to be replayed too! But not logged currently
- How to replay history in a single phase (log scan)?
- When undoing a physical op, append an redo log, called *compensation log*, for such undo in LogMgr
- Then, during recovery, RecoveryMgr can simply replay history by redoing *both* physical and compensation logs
 - In the order they appear in the log file (*from checkpoint to tail*)

REDO-UNDO Recovery Algorithm V1

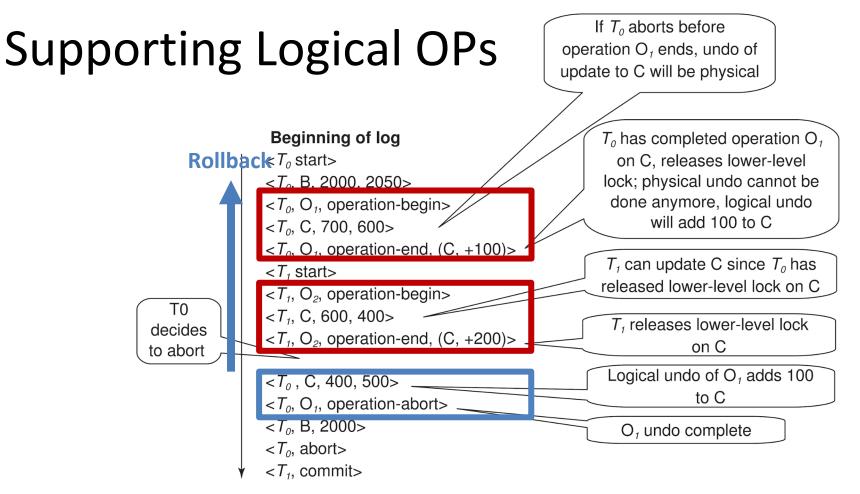

- Assuming no logical ops
- Incomplete txs are identified during the REDO phase and kept into a undo list

REDO-UNDO Recovery Algorithm V1

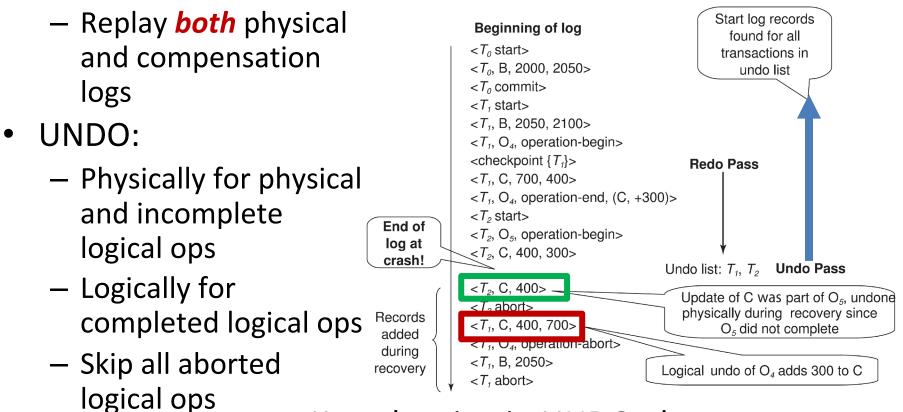

Can handle repeated crashes during recovery

 Although some redos and undos may be unnecessary

- Repeating history (REDO) carries out physical ops following the exact order they happened
- Good for dependent physical ops

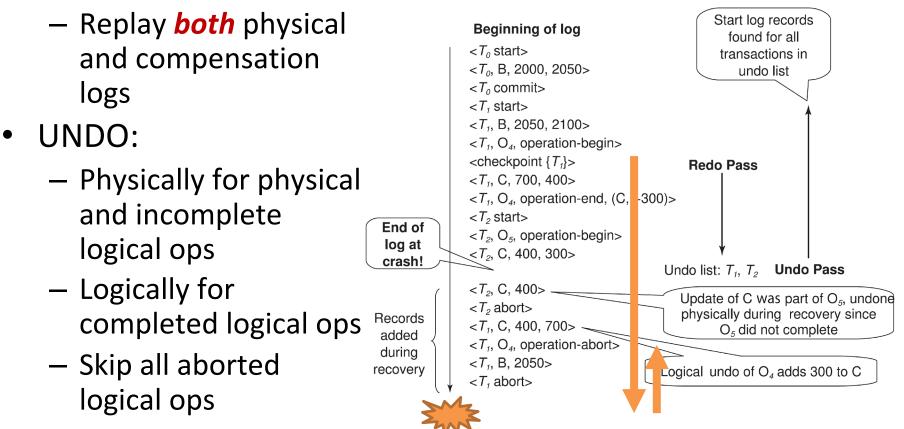

REDO-UNDO Recovery Algorithm V2

• REDO: repeat history

- Keep logging in UNDO phase:
 - Compensation logs for physical undos
 - Physical logs for a logical undos

REDO-UNDO Recovery Algorithm V2

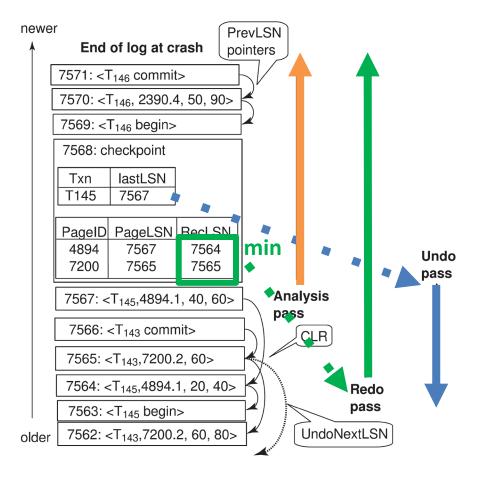

• REDO: repeat history

Non-Idempotent Logical OPs

- Note that logical operations, and their logical undos, are *not* idempotent
- Completed logical ops and logical undos are repeated using physical logs
 - In REDO phase
 - "history" grows
- So, UNDO phase must skip completed logical undos
 - When rolling back a tx, we, upon finding a record <OPABORT, Ti, Oj>, need to skip all preceding records (including OPEND record for Oj) until <OPBEGIN, Ti, Oj>
 - An operation-abort log record would be found only if a tx that is being rolled back had been partially rolled back earlier

Faster Checkpointing

- Active tx list
 - Most recent LSN for each tx
- List of dirty pages
 - RecLSN: latest log reflected to disk
 - PageLSN
- No flushing pages

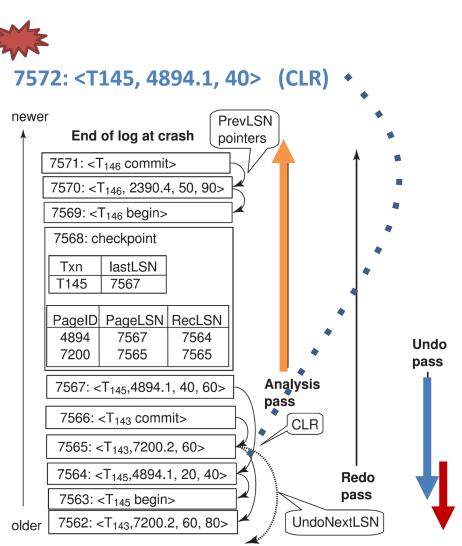

Resume Rollbacks

- How to resume rolling back all incomplete txs in UNDO phase?
- For each incomplete tx:
 - Completed logical undos must be skipped (discussed earilier)
- In addition, completed physical undos can be skipped
 - Optional; just for better performance

PrevLSN and UndoNextLSN Pointers

- Logging:
 - Each physical log keeps the PrevLSN
 - Each compensation log keeps the UndoNextLSN
- RecoveryMgr
 - Remembers the last UndoNextLSN of each tx in the undo list
 - The next LSN to process during UNDO phase is the max of the UndoNextLSNs
- Tx rollback can be resumed

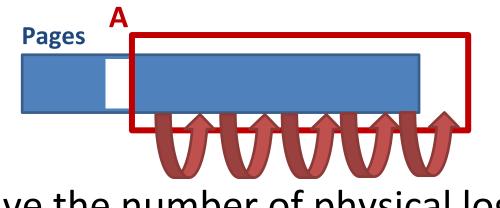

Outline

- Physical logging:
 - Logs and rollback
 - UNDO-only recovery
 - UNDO-REDO recovery
 - Failures during recovery
 - Checkpointing
- Logical logging:
 - Early lock release and logical UNDOs
 - Repeating history
- Physiological logging
- RecoveryMgr in VanillaCore

Problems of Physical Logging

- Physical logs will be huge!
- For example, if the system wants to insert a record into a sorted file
 - Common when maintaining the indices

How to save the number of physical logs?

Physiological logging

- Observe that, during a sorting op, all physical ops to the same block will be written to disk in just one flush
- Why not log all these physical ops as one logical op?
 As long as this logical op can be undone logically
- Called *physiological logs*, in that
 - Physical across blocks
 - Logical within each block
- Significantly save the cost of physical logging
- But complicates recovery algorithm further
 - As REDOs are *not* idempotent anymore
 - Need to avoid repeated replay

REDO-UNDO Recovery Algorithm V3

 During REDO, *skip* all physiological ops and their compensations that have been replayed previously

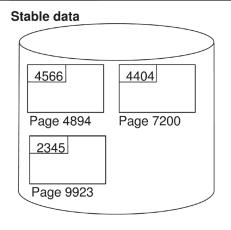

- How?

- During UNDO, threat each physiological op as physical
 - Write compensation log that is also a physiological op

Avoiding Repeated Replay

- Keep a PageLSN for each block
 - Most recent log for that block
- REDO phase:
 - Replay a physiological log iff its LSN is larger than the PageLSN of the target block
- Further optimized in ARIES

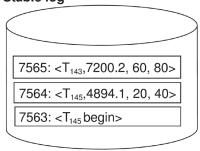

PageID	PageLSN	RecLSN
4894	7567	7564
7200	7565	7565

Dirty Page Table

7567: <t<sub>145,4894.1, 40, 60></t<sub>		
7566: <t<sub>143 commit></t<sub>		

Log Buffer (PrevLSN and UndoNextLSN fields not shown)

Stable log

Outline

- Physical logging:
 - Logs and rollback
 - UNDO-only recovery
 - UNDO-REDO recovery
 - Failures during recovery
 - Checkpointing
- Logical logging:
 - Early lock release and logical UNDOs
 - Repeating history
- Physiological logging
- RecoveryMgr in VanillaCore

The VanillaDB Recovery Manager

- Log granularity: values
- Implements **ARIES** recovery algorithm
 - Steal and non-force
 - Physiological logs
 - No optimizations
- Non-quiescent checkpointing (periodically)
- Related package
 - storage.tx.recovery
- Public class
 - RecoveryMgr
 - Each transaction has its own recovery manager
